Computing Diverse Optimal Stable Models

Javier Romero, Torsten Schaub, and Philipp Wanko

No Institute Given

Abstract. We

1 Introduction

- Answer Set Programming (ASP; [1]) has become a prime paradigm for solving combinatorial problems in the area of knowledge representation and reasoning.
- As a matter of fact, such problems have an exponential number of solutions in the worst-case.

A first means to counterbalance this is to impose a preference relation among solutions in order to filter out optimal ones.

Often enough, this still leaves us with a large number of optimal models.

- A typical example is the computation of Pareto frontiers for multi-objective optimization problems, as we encounter in design space exploration [2] or timetabling [3].
- Other examples include product configuration, planning, and phylogeny, as dis-specifics about the application areas cussed in [4].
- This calls for computational support that allows for identifying small subsets of diverse solutions.
- The computation of diverse answer sets was first considered in [4].
- The analogous problem regarding optimal answer sets is addressed in [5] in the context of answer set optimization [6]
- Beyond ASP, the computation of diverse solution is also studied in SAT [7] and CP [8].
- Contributions

•

2: TO BE FILLED

• Last but not least, our framework is easily customizable thanks to its implementation via multi-shot solving techniques. In particular, this abolishes the need for internal solver modifications that were partly necessary in previous approaches. We have implemented our approach as an extension to the preference handling framework *asprin*.

asprin

 Although we concentrate on diversity, our approach applies just as well to to its dual concept of *similarity*. (This is also reflected by its implementation supporting both settings.)

e[0] f[0] t[0] d[0] s[2.0.0]

Background

In ASP, problems are described as logic programs, which are sets of rules of the form

$$(a_0):-a_1,\ldots,a_m,$$
 not $a_{m+1},\ldots,$ not a_n

where each a_i is a propositional atom and not stands for *default negation*. We call a rule a fact if n=0, and an integrity constraint if a_0 is omitted. Semantically, a logic program induces a collection of stable models, which are distinguished models of the program determined by stable models semantics; see [10] for details.

To facilitate the use of ASP in practice, several extensions have been developed. First of all, rules with variables are viewed as shorthands for the set of their ground instances. Further language constructs include conditional literals and cardinality constraints [11]. The former are of the form $a:b_1,\ldots,b_m$, the latter can be written as $s\{c_1, \ldots, c_n\}t$, where a and b_i are possibly default-negated literals and each c_i is a conditional literal; s and t provide lower and upper bounds on the number of satisfied literals in the cardinality constraint. The practical value of both constructs becomes apparent when used with variables. For instance, a conditional literal like a (X):b(X) in a rule's antecedent expands to the conjunction of all instances of a (X) for which the corresponding instance of b (X) holds. Similarly, 2 { a (X) : b (X) } 4 is true whenever at least two and at most four instances of a (X) (subject to b (X)) are true.

Finally, objective functions minimizing the sum of weights w_i of conditional literals c_i are expressed as #minimize $\{w_1: c_1, \ldots, w_n: c_n\}$.

- Specifically, we rely in the sequel on the input language of the ASP system clingo [12]; further language constructs are explained on the fly.
- In what follows, we go beyond plain ASP and deal with *logic programs with pref*erences.

More precisely, we consider programs P over some set A of atoms along with a strict partial order $\succ \subseteq \mathcal{A} \times \mathcal{A}$ among their stable models.

Given two stable models X, Y of $P, X \succ Y$ means that X is preferred to Y.

Then, a stable model X of P is optimal wrt \succ , if there is no other stable model Y such that $Y \succ X$.

- In what follows, we often leave the concrete order implicit and simply refer to a program with preferences and its optimal stable models.
- 3Note that an empty order yields all stable models of a program. Hence, our contributions also apply to this base case without further mention.
- \blacksquare For simplicity, we consider a Hamming distance between two stable models X,Y other choices are possible of a program P over A, defined as $d(X,Y) = |A - X - Y| + |X \cap Y|$.
- Given a logic program P with preferences and a positive integer n, we follow [4] in defining a set \mathcal{X} of (optimal) stable models of P as most diverse, if $\min\{d(X,Y) \mid$ $X, Y \in \mathcal{X}, X \neq Y$ > min{ $d(X, Y) \mid X, Y \in \mathcal{X}', X \neq Y$ } for every other set \mathcal{X}' of (optimal) stable models of P.
- We are thus interested in the following problem: Given a logic program P with preferences and a positive integer n, find n most diverse optimal stable models of P.

4 T: Neededd...?:

3 T: Needed...?

- For representing logic programs with complex preferences and computing their optimal models, we built upon the preference framework of asprin [9], a system for dealing with aggregated qualitative and quantitative preferences.
- In asprin, the above mentioned preference relations are represented by declarations of the form $\#preference(p,t)\{c_1,\ldots,c_n\}$ where p and t are the name and type of the preference relation, respectively, and each c_i is a conditional literal¹ serving as arguments of p.

The directive #optimize (p) instructs asprin to search for stable models that are optimal wrt the strict partial order \succ_p associated with p.

While asprin already comes with a library of predefined primitive and aggregate preference types, like subset or pareto, respectively, it also allows for adding customized preferences.

To this end, users provide rules defining an atom better (p) that indicates whether $X \succ_{p} Y$ holds for two stable models X, Y.

The sets X and Y are provided by asprin in reified form via unary predicates holds and holds'.2

The definition of better (p) then draws upon the instances of both predicates for deciding $X \succ_{p} Y$.

- Finally, we investigate whether the heuristic capacities of clingo allow for boosting our approach.

fact, clingo 5 features heuristic directives of the '#heuristic c. [k,m]' where c is a conditional atom, k is a term evaluating to an integer, and m is a heuristic modifier among init, factor, level, sign, true, or false, respectively.

The effect of the heuristic modifiers is to bias the score of clasp's heuristic by initially adding or multiplying the score, prioritizing variables, or preferably assigning a truth value. Modifiers true and false combine level with a positive and negative sign selection, respectively.

The value of k serves as argument to the respective modification.

A more detailed description can be found in [13].

5 JR: a running example would be nice

Our diversification framework at a glance

- We summarize the methods developed, and the contributions.

3.1 Basic solving techniques

() 1. Maxmin Optimization in asprin

- Definition of preference type maxmin: Given a set of #sum aggregates, maxmize the value of the aggregate with the minimum value among all in the

See [9] for more general preference elements.

That is, holds (a) (or holds'(a)) is true iff $a \in X$ (or $a \in Y$).

e[0] f[2] t[0] d[0] s[3.2.0]

- Implementation of the preference type in asprin.

Related Work: Nothing special.

- Contributions: Definition of preference type, and implementation in asprin.

2. Guess and Check in *clingo*

- Framework defined by [14] for representing and solving Σ_2^p problems.
- Problem: Given two logic programs P and Q, P guesses and stable model X, and X is a solution if $Q \cup X$ is unsatisfiable.
- Method: Tanslation to disjunctive logic programming, using the reification techniques and the metaencoding of metasp [15]
- Implemented by a Python script.
- Application in asprin for translating a normal logic program with preferences into a disjunctive logic program: asprin translates a logic program with preferences into a guess and check problem, which is then translated into a disjunctive logic program by the Python script.
- Related Work: [14] devised the framework, and [?] the implementation techniques for *clingo*.
- Contributions: Implementation of the framework [14] for clingo, using the techniques of metasp [15]. Application to asprin. Cu Pyg,

3. Solving queries in asprin:

- Problem: Find an optimal model of a program P with preferences, that satisfies a query atom q
- Methods:
 - (a) Enumerate all *optimal models* of P until one satisfies q
 - (b) Enumerate all *models* of $P \cup \{\bot \leftarrow not \ q\}$ and test each for optimality
 - (c) Enumerate all optimal models of $P \cup \{\bot \leftarrow not \ q\}$ and test each for optimality convergence
- (d) Modify asprin improving algorithm, adding alternatively $\{\bot \leftarrow not \ q\}$ or
- Related Work: Truczcynski et al. defined and implemented the first two meth-
- ods with aso preferences, for computing an optimal model that is at a distance less or equal than k of another stable model.
- Contributions: Solve queries for asprin preferences in general, and propose two more methods.
- 4. Preferences over optimal models in *asprin*:
 - Problem: Given a logic program with preferences P, and a preference specification s find, among the optimal models of P, one that is optimal wrt s.
 - Method: First, compute an optimal model of P. Then, compute iteratively optimal models of P that are better than the last one wrt s, until no one exists, in which case the last one is a solution.
 - Implementation: Iterative algorithm around asprin. The condition of being better than the last optimal model is posed as a query, and at every step asprin tries to find an optimal model that satisfies the query.
 - Related Work: iterative method is well known.
 - Contributions: Define problem, methods and implement.

()

e[0] f[2] t[0] d[0] s[3.2.0]

Advanced diversification techniques 3.2

- Enumeration:

- Step 1: Enumerate all optimal models of the logic program P with preferences.
- Step 2: Find among all optimal models already computed, those n which are most diverse.
- Implementation: Step 1 is implemented via asprin enumeration mode, step 2 is implemented by a logic program with preferences.
- Related work: The method appears in (Eiter et al., ICLP 2009) for logic programs without preferences.
- Contributions: Extension of the method of (Eiter et al., ICLP 2009) to logic programs with preferences (this is trivial), and implementation in asprin.

- Replication:

- Step 1: Translate the logic program with preferences P into a disjunctive logic program D applying the guess and check method in asprin
- Step 2: Reify D into R_D , and add a metaencoding M replicating P, such that every stable model of the metaencoding along with the reified program $(R_D \cup$ M), corresponds to n optimal models of the original logic program P.
- Step 3: Add a maxmin preference statement s such that the optimal stable models of $R_D \cup M \cup s$ correspond to n most diverse optimal stable models of the original program P.
- Related Work: The method appears in (Eiter et al., ICLP 2009) for logic programs without preferences, but it is not automated, i.e., the user must modify himself the program P for having n solutions per stable model.
- Contributions: Automation of the method of (Eiter et al., ICLP 2009), and extension to logic programs with preferences. Method for replicating a logic program (Step 2), and maxmin preference statement for selecting most diverse optimal models (Step 3).
- Approximation: We propose different techniques, which are variations of Algorithm 1.

Vall of

```
Algorithm 1: iterative(P, n)
              : P is a logic program with preferences, n is a positive integer
  Output: A set of solutions of P, or \bot
1 \mathcal{X} = \{solve(P, \emptyset)\};
2 while test(\mathcal{X}) do
  \mathcal{X} = \mathcal{X} \cup solve(P, \mathcal{X});
4 return solution(\mathcal{X});
```

In the basic case, $test(\mathcal{X})$ returns true until there are n solutions in \mathcal{X} , $solution(\mathcal{X})$ returns the set \mathcal{X} , and the algorithm simply computes n solutions by calling $solve(P, \mathcal{X})$. This can be further elaborated.

The techniques differ in the procedure $solve(P,\mathcal{X})$:

dishuct

1 Comprex

we disher 10 12 10 do s[4.0.0] we disher 10 cases

- 1. $solve(P, \mathcal{X})$ returns an optimal model of P most dissimilar to those in \mathcal{X} .
 - Method: Define a maxmin preference statement s maximizing the minimal distance to any of the solutions in X. Add s to P for computing among the optimal models of P, one that is optimal wrt s.

6 JR: I didn't manage to write this nicer.

• Related Work: The method appears in (Eiter et al., ICLP 2009) for logic programs without preferences.

- Contributions: Extension of the method of (Eiter et al., ICLP 2009) to logic programs with preferences, applying the method for preferences over optimal models of *asprin* that uses the method for queries on *asprin*
- 2. $solve(P, \mathcal{X})$ computes a partial interpretation I distant to \mathcal{X} , and returns an optimal model of P most similar to I.
 - Step 1: Select a partial interpretation *I* in one of the following ways:
 - * A random one
 - * The best according to pquide heuristic from (A. Nadel, SAT 2011).
 - * The most dissimilar to the solutions in \mathcal{X} (using ASP for the computation).
 - * Different to the last optimal model computed, taking into account either true atoms, or false atoms, or both.
 - Step 2: Define a less(cardinality) preference statement s minimizing the distance to I. Add s to P for computing among the optimal models of $P \cup \{s\}$ one that is optimal wrt s.
 - Related Work: Truczcynski et al. defined and implemented two methods with aso preferences, for computing an optimal model that is at a distance less or equal than k of another stable model.
 - Contributions: The method seems novel. <
- 3. $solve(P, \mathcal{X})$ returns any optimal model (not in \mathcal{X}).
- (4). Combining heuristics with the previous methods.
 - For technique 2, fix the sign of the atoms to their value in the selected partial interpretation *I*.
- For technique 3, select a partial interpretation I as for technique 2, and fix the sign of the atoms to their value in I.
 - For techniques 1 to 3, apply a dynamic heuristic. This heuristic, when the current assignment is very close to a previous solution, modifies the signs to get away from it.
 - Furthermore, different priorities may be given to the atoms.
- Note: enumeration and replication are complete, while approximation is not.

4 Maxmin optimization in asprin

- All methods apply maxmin optimization via asprin preference type maxmin.
- asprin preference type maxmin is defined as: dom(maxmin) is $\mathcal{P}(\{g,w,t:F\})$, where g and w are integers, and t is a term tuple, F is a boolean formula, and \mathcal{P} stands for the power set. We say that g appears in E if there is some preference element with g as the first term. Given a set of preference elements of that form, maxmin maps these elements to the preference relation defined as follows. Given

ale d'inter

S, minut

e[0] f[2] t[0] d[1] s[5.0.0]

paper.tex 6/04/2016 at 22:48 page 7 #9

an stable model X, a set of preference elements E, and an integer g standing for a group, let w(X, E, q) be

$$\sum_{(w,t)\in\{w,t\mid g,w,t:F\in E,X\models F\}}w$$

Then

X > Y if $\min\{w(X, E, g) \mid g \text{ appears in } E\} > \min\{w(Y, E, g) \mid g \text{ appears in } E\}$

- Switching the signs of the weights in the preference statements, we get minmax preference, and with only one group, it reduces to more(weight) (or less(weight), swithcing the signs).
- The preference type is implemented by the following preference program:

```
#program preference(maxmin).
%%% gather groups
group(P,G) :- preference(P,maxmin), preference(P,_,_,_,(G,W,T)).
%%% holds must be better
better(P) :- preference(P, maxmin),
             better (P,G): group (P,G).
better(P,G) :- preference(P, maxmin), group(P,G), valueh'(P,V),
               V < #sum \{ W,T : holds(X), preference(P,_,_,for(X),(G,W,T)).
%%% get min value for holds'
valueh'(P,G,V):- preference(P,maxmin), group(P,G),
                  V = #sum \{ W,T : holds'(X), preference(P,_,_,for(X),(G,W,T)
valueh'(P,V) :- preference(P,maxmin), V = #min { VV : valueh'(P,G,VV) }.
```

- The naive implementation of this preference in clingo via #minimize statements, leads to large groundings, in the longer version of this papers we investigate other possible encodings, and compare them with the asprin implementation.

Guess and Check in clingo

7

Definition 1 (Guess and Check [14]). Let P and Q be two logic programs, and X an they use interpretation of P. X is a guess and check solution for $\langle P, Q \rangle$ if X is a stable model of P and $\{holds'(a) \mid a \in X\} \cup Q$ is unsatisfiable.

7 JR: This is exactly Eiter and Polleres paper :(, I changed 'guess and check' to 'guess and check', the name

- Guess and Check (GT) is a useful setting for representing problems at the second level of the polynomial hierarchy. 8
- Example (quantified boolean cnf). Let $\exists X \forall Y \phi$ be a quantified boolean CNF for-here, but I don't know mula, where ϕ is a CNF formula over atoms $X \cup Y$ such that $X \cap Y = \emptyset$. This go. The first (2QCNF) is can be represented in ASP via facts:

April 6, 2016 — $LastChangedRevision: 42 \bullet \bullet \bullet$

8 JR: I put three examples whether the first two should good for proving the hardness of the problem, the second (conformant planning) shows how to p7:#9 — $\bigcirc_R \bigcirc_M$ represent easily an interesting problem, and the third is asprin. JR: Eiter and Polleres have 2QDNF, conformant planning and strategic JR: Eiter and Polleres to

DNF, instead of CNF

```
\bullet clause (C): for every clause C in \phi
```

- exists (V): for every variable $V \in X$
- forall (V): for every variable $V \in Y$
- pos (C, V): for every positive literal V in clause C.
- neg (C, V): for every negative literal V in clause C.

Let P be the program:

```
{ holds(X) : exists(X) }. and Q be the program: 
{ holds(X) : forall(X) }. bot :- clause(C); not holds(X) : pos(C,X); holds(X) : neg(C,X). :- not bot. holds(X) :- holds'(holds(X)).
```

The guess and check solutions of $\langle P,Q\rangle$ correspond one to one to the models of $\exists X \forall Y \phi$. The atom bot holds if the interpretation of the variables in $X \cup Y$ is not a model of ϕ . Informally, P guesses a solution S, then if $\{holds'(a) \mid a \in S\} \cup Q$ is unsatisfiable, there is no interpretation of the atoms in Y that makes ϕ false, which means that for all interpretations of the atoms in Y, ϕ is true, and the boolean formula holds.

- Example (conformant planning). In Let $C = \langle F, A, T, I, G, n \rangle$ be a conformant of the want this to planning problem with fluents F, actions A, transition function $T: F \times A \to F$, stay, I can make it much initial fluents $I \subseteq F$, goal fluent $G \in F$, and a positive integer n representing the plan length. The transition function T induces a transition diagram $D_T = \langle S, E \rangle$ with states $S = \{s \mid s \subseteq F\}$ and arcs from s_1 to s_2 labelled by a if $T(s_1, a) = s_2$. A solution to C is a sequence of actions $a_1, a_2, \ldots, a_{n-1}, a_n$ such that for all possible states $I' \in S$, if $I \subseteq I'$ then there is a path of length n in D_T from I' to a state s_f such that $g \in s_f$. Let P_T be a logic program representing all paths of length n in the D_T . Predicate holds (F, T) stands for fluent F being true at state T of the path, and occurs (A, T) stands for action A connecting states T-1 and T of the path. Let P be the program:

```
{ occurs(A,T) : action(A) } :- T=1..n.
and Q be the program:
:- not holds(F,0), initial(F).
:- holds(goal,n).
:- not occurs(A,T), holds'(occurs(A,T)).
```

The guess and check solutions of $\langle P,Q \cup P_T \rangle$ correspond one to one to the conformant plans of the problem.

- Example. Preferences in asprin. Let P be a logic program with signature A, let s be a preference statement defining preference relation \succ_s over $A \times A$, and Q a preference program for s. The guess and check solutions of $\langle P, P \cup Q \cup \{holds(a) \leftarrow a \mid a \in A\} \rangle$ correspond to the \succ_s -preferred stable models of P.
- Implementation. III

11 JR: I copy the explanation from the Draft of Preferences

 $p8:#11 - \bigcirc_R \bigcirc_M$

- Eiter and Gottlob invented the *saturation* technique. The idea is to re-express the problem as a positive disjunctive logic program, containing a specialpurpose atom bot. Whenever bot is obtained, saturation derives all atoms (belonging to a "guessed" model). Intuitively, this is a way to materialize unsatisfiability. For automatizing this process, we build upon the meta-interpretationbased approach in [15]. The idea is to map a program R onto a set $\mathcal{R}(R)$ of facts via reification. The set $\mathcal{R}(R)$ of facts is then combined with a meta-encoding \mathcal{M} from [15] implementing saturation.
- In our case, we consider for a GT problem $\langle P, Q \rangle$ the positive disjunctive logic program

$$\mathcal{R}(Q \cup \{\{holds'(a)\} \mid a \in \mathcal{A}_{\mathcal{P}}\}) \cup \mathcal{M}.$$

- This program has a stable model (excluding bot) for each $X \subseteq \mathcal{A}_{\mathcal{P}}$ such that $\{holds(a) \mid a \in X\} \cup Q \text{ is satisfiable, and it has a saturated stable model } \}$ (including bot) if there is no such X.
- \bullet For computing a solution to the GT problem, one just has to add the generator program P, map the atoms of P to their names in the positive disjunctive logic program, and inforce the atom bot

$$P \cup \mathcal{R}(Q \cup \{\{holds'(a)\} \mid a \in \mathcal{A}_{\mathcal{P}}\}) \cup \mathcal{M} \cup \{holds(a) \leftarrow a \mid a \in X\} \cup \{not \ holds(a) \leftarrow not \ a \mid a \in X\} \cup \{\leftarrow \ not \ bot\} \ .$$

- Deciding whether there is a solution to a GC problem is Σ_2^p -complete. Membership $\frac{holds(a)}{pot}$ and comes from the translation to disjunctive logic programming, and hardness comes exactly like that, I have to go from the translation from quantified boolean CNF formulas.
- Differences with [14]: 13
 - Our encoding avoids "guessing" a level mapping to describe the formation of differences stated in metasp a counterexample, but directly denies models for which there is no such construction, i
 - Notably, our meta-programs apply to (reified) extended logic programs (Simons et al. 2002), possibly including choice rules and #sum constraints, and we are unaware of any existing meta-encoding of their answer sets, neither as candidates nor as counterexamples refuting optimality

In this section, we implement Eiter and Polleres framework with the metaencoding and reification of metasp. 14

Solving queries in asprin

Definition 2 (Query Problem). Let P be a logic program over A, let s be a preference programs P and Q to CNF, statement, and q an atom of A, decide if any \succ_s -preferred stable model of P contains and then calling a QBF q.

15

Definition 3 (Query Problem). Let P be a logic program over A, let s be a preference becomes another paper... statement, and q an atom of A, find a \searrow -preferred stable model of P containing q.

12 JR: The rules generating $not\ holds(a)$ are not again through it.

13 JR: Copied from the paper

14 JR: Not much... If we wanted, one way to go would be giving another implementation (maybe for the long paper, I dont now?) An easy one is using Tomi's tools to translate logic solver. Another, which I'd really like to do, is doing it right inside clasp, with two interleaved solvers (maybe with SMT?) But I guess that

```
Algorithm 2: solveOpt(P, s, t)

Input : A program P over \mathcal{A} and preference statements s and t.

Output : A \succ_{s,t}-preferred stable model of P, if P is satisfiable, and \bot otherwise.

1 Y \leftarrow solveOpt(P, s);
2 if Y = \bot then return \bot;
3 repeat
4 | X \leftarrow Y;
5 | Y \leftarrow solveOptq(P \cup q(E_{t_t} \cup F_t \cup R_{\mathcal{A}} \cup holds'(X)), q) \cap \mathcal{A};
6 until Y = \bot;
7 return X
```

8 Complete methods

8.1 Enumeration

- Enumerate all optimal stable models of *P* with *asprin*, and afterwards find, among all those stable models, the *n* most diverse (with *asprin* again).
- This method may be exponential in space, given that we may have to compute and store an exponential number of solutions.
- For the first step, we simply enumerate all optimal stable models of P with asprin.
- For the second step, let $\mathcal{X}=\{X_1,\ldots,X_m\}$ be the set of m optimal stable models of P. This set may be represented in ASP via the set of atoms $A_{\mathcal{X}}=\{holds(a,i)\mid a\in X_i\}$. Consider the *asprin* encoding E:

19 JR: I put two encodings, the first one for asprin 1.0, the second (nicer) for asprin

```
n { select(I) : model(I) } n.
#preference(p,maxmin) {
    (I,J),1,X :: select(I) & select(J) :
holds(A,I), not holds(A,J), model(I), model(J), I < J;
    (I,J),1,X :: select(I) & select(J) : not holds(A,I),
holds(A,J), model(I), model(J), I < J
}.</pre>
```

Consider the *asprin* encoding E:

Then the optimal stable models of $A_{\mathcal{X}} \cup E$, computed by *asprin*, correspond to most diverse solutions of P.

```

8.2 Replication

- First, translate the *normal* input logic program with preferences P into a disjunctive logic program without preferences D_P using asprin. This is done applying a general framework for generate and test in ASP.
- Second, reify the resulting logic program with reify tool into a set of facts F_{D_P} .
- Consider a metaencoding meta such that the stable models of $F_{D_P} \cup meta$ correspond one to one to the stable models of D_P .
- For the case where D_P contains no choice rules or weight constraints, meta is:

- Consider metaencoding meta(n) such that given a positive integer n, from every stable model of $F_{D_P} \cup meta(n)$, n stable models of P may be extracted.
- More technically, the stable models of $F_{D_P} \cup meta(n)$ correspond one to one to the elements of the set $SM(D_P) \times ... \times SM(D_P)$, where $SM(D_P)$ stands for

the set of stable models of D_P .

- For the case where D_P contains no choice rules or weight constraints, meta(n) is:

Note that with this basic encoding every set of n models will appear in n! stable
models. For having one stable model for every set of n models, we add the following set of rules:

```
TO BE ADDED
```

 For computing most diverse solutions, we add the following preference specification:

```
#optimize(p).
#preference(p, maxmin) {
    (I, J), 1, X : hold(A, I), not hold(A, J), model(I), model(J), I < J;
    (I, J), 1, X : not hold(A, I), hold(A, J), model(I), model(J), I < J
}.</pre>
20 JR: If we decide to keep
```

- This method does not work if P is disjunctive.

the encodings, I can choose better predicates or print them nicer.

9 Approximation

21

21 JR: I made no changes after this point.

The following methods approximate n most dissimilar solutions. They are variations of Algorithm 3.

```
Algorithm 3: iterative(P, n)

Input : P is a logic program possibly with preferences, n is a positive integer

Output : A set of solutions of P, or \bot

1 \mathcal{X} = \{solve(P, \emptyset)\};

2 while test(\mathcal{X}) do

3 \bigcup \mathcal{X} = \mathcal{X} \cup solve(P, \mathcal{X});

4 return solution(\mathcal{X});
```

In the basic case, test(X) returns true while there are less than n solutions in X, solution(X) returns the set X, and the algorithm simply computes n solutions by calling solve. This can be further elaborated. For example, test(X) may return true until k ($k \geq n$) solutions are in X, and solution(X) returns the n most dissimilar solutions among those in X. The algorithm is complete if test(X) returns true until all solutions have been computed (in which case the algorithm reduces to **enumerate all** above).

The methods differ in the implementation of the solve(P,n) call. Below, every method is more imprecise than the previous ones, i.e. the solutions given are more similar than with the previous methods.

9.1 Find a solution most dissimilar to those in \mathcal{X} .

_ 3

- Add maxmin optimization to P to compute a solution that maximizes the minimal distance to any of the solutions in X.
- Implementation: Without preferences, using Maxmin Optimization (see next subsection). With preferences, using the method for preferences over asprin, that uses the method for queries (see next subsection).

9.2 Consider a partial interpretation I distant to \mathcal{X} , and find a solution close to I.

_ 4

³ For future work, when test(X) allows computing more than n solutions, we could find a solution along with at most n-1 solutions in X, such that they altogether are most dissimilar. In this way, we make choices on the solution we look for, and on which of the previous solutions are also selected.

⁴ For future work, one could consider looking for a solution close to I for a number of conflicts, and if no solution is found, pick another partial interpretation I' and continue from there.

- Select a partial interpretation *I*:
 - 1. A Random one.
 - 2. According to pguide heuristic from (A. Nadel, SAT 2011). An atom is true if among the solutions in \mathcal{X} it is false more times than true, and it is false in the opposite case. In case of a tie, it does not appear in I.
 - 3. The most dissimilar to the solutions in \mathcal{X} (computed using maxmin optimization in ASP).
 - 4. Different to the last added element L of \mathcal{X} (for this, \mathcal{X} should be a list). I may be the result of changing all signs of L ($\{\neg a \mid a \in L\} \cup \{a \mid \neg a \in L\}$), or taking only the positive atoms of L and changing the signs ($\{\neg a \mid a \in L\}$), or similarly with the negative atoms of L ($\{a \mid \neg a \in L\}$).
- Apply minimization to compute a solution as close to I as possible.
- Implementation: Without preferences, using normal optimization. With preferences, using the method for preferences over asprin, that uses the method for queries (see next subsection).

9.3 Find any solution of P.

- No optimization here, but we expect that heuristics alone give a good approximation.
- Implementation: Without preferences, add a rule to delete the last model. Alternatively, we can simply enumerate models. With preferences, use asprin option --input-optimal to delete the last computed optimal models, and all models worse than them. Alternatively, we can simply enumerate optimal models.

9.4 Heuristics

They may be combined with any of the previous three methods:

- Fix the sign of the atoms to their value in a partial interpretation I selected by any
 of the methods above (1–4).
- Adding to modifying the signs, give priority 1 to the atoms relevant for dissimilarity, or to the atoms in the partial interpretation I. Furthermore, different priorities may be given depending on the pguide heuristic value (i.e., the priority of atom a is $abs(|\{Y \in \mathcal{X} | a \in Y\}\}| |\{Y \in \mathcal{X} | \neg a \in Y\}\}|)$).
- Adding to modifying the signs, apply the dynamic heuristic. This heuristic, when the current assignment is very close to a previous solution, modifies the signs to get away from it.
- Different default sign heuristics could also be tried. For example, it would be interesting to try a random sign heuristic.
